0.0.1 Diabetes Prediction Model using Stacking Algorithm

[ ]:

```

```

[1]:

```
# importing the data.

import pandas as pd
diabetes_data = pd.read_csv(r"C:\Users\DELL\Documents\MACHINE LEARNING\diabetes.
  ↪csv")
print(diabetes_data)
```

```
     Pregnancies  Glucose  BloodPressure  SkinThickness  Insulin   BMI  \
0              6      148             72             35        0  33.6
1              1       85             66             29        0  26.6
2              8      183             64              0        0  23.3
3              1       89             66             23       94  28.1
4              0      137             40             35      168  43.1
..           …      …            …            …      …   …
763           10      101             76             48      180  32.9
764            2      122             70             27        0  36.8
765            5      121             72             23      112  26.2
766            1      126             60              0        0  30.1
767            1       93             70             31        0  30.4

     DiabetesPedigreeFunction  Age  Outcome
0                       0.627   50        1
1                       0.351   31        0
2                       0.672   32        1
3                       0.167   21        0
4                       2.288   33        1
..                        …  …      …
763                     0.171   63        0
764                     0.340   27        0
765                     0.245   30        0
766                     0.349   47        1
767                     0.315   23        0

[768 rows x 9 columns]
```

[2]:

```
# to check whether data is balanced or not?

diabetes_data['Outcome'].value_counts()
```

[2]:

```
Outcome
0    500
1    268
Name: count, dtype: int64
```

Hence, it’s an imbalanced dataset, imbalanced towards class 0 i.e. No diabetes cases. So now we’ll perform a sampling technique to balance the dataset.

```

0.1 Analysis.

0.1.1 Analysis of Classification report.

An accuracy of 0.81 means that 81% of the overall predictions by the model are correct.

The precision for predicting No Diabetes is 0.78 means that 78% of the time the model predicting a case as No Diabetes is correct.

The precision for predicting Diabetes is 0.84 means that 84% of the time the model predicting a case as Diabetes is correct.

Recall for No Diabetes is 0.84 means that the model can recognize 84% of all the No Diabetes cases.

Recall for Diabetes is 0.78 means that the model can recognize 78% of all the Diabetes cases.

F-1 scores for No diabetes and Diabetes is 0.81, indicating a good balance between precision and recall for both classes & a balanced model's prediction for both case types.

Support of 93 and 101 samples for No Diabetes and Diabetes classes respectively indicates that the dataset is relatively balanced between both classes.

Hence, the model is performing effectively in predicting both cases.

0.1.2 Analysis of Confusion Matrix.

True Positive(TP)- 79, it's the number of times a diabetes case is correctly predicted as diabetes.

True Negative(TN)- 78, it's the number of times a no diabetes case is correctly predicted as no diabetes.

False Positive(FP)- 15, it's the number of times a no diabetes case is incorrectly predicted as diabetes.

False Negative(FN)- 22, it's the number of times a diabetes case is incorrectly predicted no diabetes

The above values from the confusion matrix indicate that-

The model correctly predicts 79 instances of diabetes and 78 instances of no diabetes.

It incorrectly identifies 15 no diabetes cases as diabetes and 22 diabetes cases as no diabetes.

Hence, the model is effective in predicting both cases but still there is some room for improvement and false positive and false negative cases can be reduced further.

0.1.3 ROC-AUC(Receiver Operating Characteristics-Area Under the Curve) Score-

ROC-AUC Score of 0.8104439476205685 indicates that a model has a good ability to distinguish between both the Diabetes and No Diabetes classes. As ROC-AUC Score ranges from 0 to 1, with 1 indicating perfect classification and 0.5 or below indicating no discriminative power.

Hence, overall the stacking model has good performance and is very effective in predicting both classes, with a slight scope for further improvement.
